## **SESSION-18**

# **HIBERNATE QUERY LANGAUGE**

# **Hibernate Query Language(HQL):**

Hibernate Query Language (HQL) is an object-oriented query language, similar to SQL, but instead of operating on tables and columns, HQL works with persistent objects and their properties. HQL queries are translated by Hibernate into conventional SQL queries, which in turns perform action on database.

Although you can use SQL statements directly with Hibernate using Native SQL, but I would recommend to use HQL whenever possible to avoid database portability hassles, and to take advantage of Hibernate's SQL generation and caching strategies.

Keywords like SELECT, FROM, and WHERE, etc., are not case sensitive, but properties like table and column names are case sensitive in HQL.

**Hibernate Query Language (HQL)** is same as SQL (Structured Query Language) but it doesn't depends on the table of the database. Instead of table name, we use class name in HQL. So it is database independent query language.

### **Advantage of HQL**

There are many advantages of HQL. They are as follows:

- database independent
- supports polymorphic queries
- o easy to learn for Java Programmer

## **Query Interface**

It is an object oriented representation of Hibernate Query. The object of Query can be obtained by calling the createQuery() method Session interface.

The query interface provides many methods. There is given commonly used methods:

- 1. **public int executeUpdate()** is used to execute the update or delete query.
- 2. **public List list()** returns the result of the ralation as a list.
- 3. **public Query setFirstResult(int rowno)** specifies the row number from where record will be retrieved.
- 4. **public Query setMaxResult(int rowno)** specifies the no. of records to be retrieved from the relation (table).
- 5. **public Query setParameter(int position, Object value)** it sets the value to the JDBC style query parameter.
- 6. **public Query setParameter(String name, Object value)** it sets the value to a named query parameter.

### **FROM Clause**

You will use **FROM** clause if you want to load a complete persistent objects into memory. Following is the simple syntax of using FROM clause –

```
String hql = "FROM Employee";

Query query = session.createQuery(hql);

List results = query.list();
```

If you need to fully qualify a class name in HQL, just specify the package and class name as follows –

```
String hql = "FROM com.hibernatebook.criteria.Employee";

Query query = session.createQuery(hql);

List results = query.list();
```

#### **AS Clause**

The **AS** clause can be used to assign aliases to the classes in your HQL queries, especially when you have the long queries. For instance, our previous simple example would be the following –

```
String hql = "FROM Employee AS E";

Query query = session.createQuery(hql);

List results = query.list();
```

The **AS** keyword is optional and you can also specify the alias directly after the class name, as follows –

```
String hql = "FROM Employee E";

Query query = session.createQuery(hql);

List results = query.list();
```

#### **SELECT Clause**

The **SELECT** clause provides more control over the result set then the from clause. If you want to obtain few properties of objects instead of the complete object, use the SELECT clause. Following is the simple syntax of using SELECT clause to get just first\_name field of the Employee object –

```
String hql = "SELECT E.firstName FROM Employee E";

Query query = session.createQuery(hql);

List results = query.list();
```

It is notable here that **Employee.firstName** is a property of Employee object rather than a field of the EMPLOYEE table.

### **WHERE Clause**

If you want to narrow the specific objects that are returned from storage, you use the WHERE clause. Following is the simple syntax of using WHERE clause –

```
String hql = "FROM Employee E WHERE E.id = 10";

Query query = session.createQuery(hql);

List results = query.list();
```

#### **ORDER BY Clause**

To sort your HQL query's results, you will need to use the **ORDER BY** clause. You can order the results by any property on the objects in the result set either ascending (ASC) or descending (DESC). Following is the simple syntax of using ORDER BY clause –

```
String hql = "FROM Employee E WHERE E.id > 10 ORDER BY E.salary DESC";

Query query = session.createQuery(hql);

List results = query.list();
```

If you wanted to sort by more than one property, you would just add the additional properties to the end of the order by clause, separated by commas as follows –

```
String hql = "FROM Employee E WHERE E.id > 10 " +

"ORDER BY E.firstName DESC, E.salary DESC ";

Query query = session.createQuery(hql);

List results = query.list();
```

#### **GROUP BY Clause**

This clause lets Hibernate pull information from the database and group it based on a value of an attribute and, typically, use the result to include an aggregate value. Following is the simple syntax of using GROUP BY clause –

```
String hql = "SELECT SUM(E.salary), E.firtName FROM Employee E " +

"GROUP BY E.firstName";

Query query = session.createQuery(hql);

List results = query.list();
```

### **Using Named Parameters**

Hibernate supports named parameters in its HQL queries. This makes writing HQL queries that accept input from the user easy and you do not have to defend against SQL injection attacks. Following is the simple syntax of using named parameters –

```
String hql = "FROM Employee E WHERE E.id = :employee_id";

Query query = session.createQuery(hql);

query.setParameter("employee_id",10);

List results = query.list();
```

#### **UPDATE Clause**

Bulk updates are new to HQL with Hibernate 3, and delete work differently in Hibernate 3 than they did in Hibernate 2. The Query interface now contains a method called executeUpdate() for executing HQL UPDATE or DELETE statements.

The **UPDATE** clause can be used to update one or more properties of an one or more objects. Following is the simple syntax of using UPDATE clause –

```
String hql = "UPDATE Employee set salary = :salary " +

"WHERE id = :employee_id";

Query query = session.createQuery(hql);

query.setParameter("salary", 1000);

query.setParameter("employee_id", 10);

int result = query.executeUpdate();

System.out.println("Rows affected: " + result);
```

#### **DELETE Clause**

The **DELETE** clause can be used to delete one or more objects. Following is the simple syntax of using DELETE clause –

```
String hql = "DELETE FROM Employee" +

"WHERE id = :employee_id";

Query query = session.createQuery(hql);

query.setParameter("employee_id", 10);

int result = query.executeUpdate();

System.out.println("Rows affected: " + result);
```

### **INSERT Clause**

HQL supports **INSERT INTO** clause only where records can be inserted from one object to another object. Following is the simple syntax of using INSERT INTO clause –

```
String hql = "INSERT INTO Employee(firstName, lastName, salary)" +

"SELECT firstName, lastName, salary FROM old_employee";

Query query = session.createQuery(hql);

int result = query.executeUpdate();

System.out.println("Rows affected: " + result);
```

## **Aggregate Methods**

HQL supports a range of aggregate methods, similar to SQL. They work the same way in HQL as in SQL and following is the list of the available functions –

Sr.No.	Functions & Description
1	avg(property name)  The average of a property's value
2	count(property name or *)  The number of times a property occurs in the results
3	max(property name)  The maximum value of the property values
4	min(property name)  The minimum value of the property values
5	sum(property name)  The sum total of the property values

The **distinct** keyword only counts the unique values in the row set. The following query will return only unique count –

```
String hql = "SELECT count(distinct E.firstName) FROM Employee E";

Query query = session.createQuery(hql);

List results = query.list();
```

# **Pagination using Query**

There are two methods of the Query interface for pagination.

Sr.No.	Method & Description
1	Query setFirstResult(int startPosition)  This method takes an integer that represents the first row in your result set, starting with row 0.
2	Query setMaxResults(int maxResult)  This method tells Hibernate to retrieve a fixed number maxResults of objects.

Using above two methods together, we can construct a paging component in our web or Swing application. Following is the example, which you can extend to fetch 10 rows at a time –

```
String hql = "FROM Employee";

Query query = session.createQuery(hql);

query.setFirstResult(1);

query.setMaxResults(10);

List results = query.list();
```

## **Example of HQL to get all the records**

```
Query query=session.createQuery("from Emp");//here persistent class name is Emp
List list=query.list();
Example of HQL to get records with pagination
Query query=session.createQuery("from Emp");
query.setFirstResult();
query.setMaxResult();
List list=query.list();//will return the records from to th number
Example of HQL update query
Transaction tx=session.beginTransaction();
Query q=session.createQuery("update User set name=:n where id=:i");
q.setParameter("n","Udit Kumar");
q.setParameter("i",);
int status=q.executeUpdate();
System.out.println(status);
tx.commit();
Example of HQL delete query
Query query=session.createQuery("delete from Emp where id=");
//specifying class name (Emp) not tablename
query.executeUpdate();
HQL with Aggregate functions
```
